

Animal Research Review Panel Guideline 27-A

Research Animal Rehoming Guideline – Alpacas

Introduction

This guide is designed to support the implementation of the Research Animal Rehoming Guidelines and can be used by everyone involved in the use of alpacas for recognised research purposes. It provides specific guidance on the assessment of research alpacas for rehoming. This guide aims to:

- assist in the assessment of whether the physiological condition and behavioural attributes of the alpacas indicate that they can be rehomed with only minimal, transient impact on their wellbeing
 - prioritise the welfare of the alpacas and the safety and satisfaction of the public
 - ensure alpacas being rehomed are fit for their intended purpose, healthy and up to date on all standard preventative care
 - ensure rehoming conforms to national, state, and local legislation and regulations.
-

Approach to rehoming

Research establishments may institute their own rehoming program, or they may partner with one or more external rehoming groups. Before assessing animals for rehoming, it is essential to decide on the avenues for rehoming, taking into consideration:

- internal resources to manage the rehoming of the animal
- agreements in place with external rehoming groups
- availability of a suitable owner or responsible organisation to:
 - maintain the animals
 - provide routine husbandry procedures, such as shearing and hoof care
 - assist with special needs of individual animals
- the capacity (number of animals) that can be rehomed via the research establishment's own rehoming program and via external rehoming groups.

Establishing good communication with rehoming groups can be beneficial as they can provide advice on:

- the likely success of rehoming
 - best methods of rehoming (such as pairing or bonding animals)
 - preparing the animals before they are released from the research establishment
 - identification of special cases and care strategies where an animal may need assistance to transition from the research environment
 - information/animal profiles needed to assist in rehoming.
-

Eligibility for rehoming

If an animal is healthy or has manageable health or behavioural issues it should be considered for rehoming.

Where animals are eligible for rehoming, assessment for rehoming should consider:

- the animal's age and life expectancy. These are not usually primary determining factors
- the animal's general and physical health and wellbeing
- the procedures the animal has been involved with and any ongoing sensitivities that may have resulted with respect to animal handling, feeding and general care. Appropriate consideration of these may include behaviour modification to improve the animal's response and/or notifying the new owners of the animal's specific sensitivities
- whether the rehoming process is likely to have minimal, transient impact on their wellbeing.

Alpacas are commonly kept and thus suitable food, care information and veterinary services are available. It is recommended that male alpacas are castrated as they tend to develop aggressive behaviours towards other alpacas and humans.

There are situations where rehoming of an animal is not an available or appropriate option. These situations should be identified in your accredited research establishment's rehoming policy.

Some of these situations will be clear before research commences, for example:

- the AEC has approved the reuse of the animal for research
- the AEC has approved the humane killing of animals for essential sample collection or testing
- laws and regulations that prohibit rehoming, for reasons such as risk to public health, biosecurity and the environment. For example, there may be restrictions on releasing animals that are genetically modified or that have been treated with certain substances (e.g. drugs, chemicals, infectious agents) and devices.

Other situations may only become apparent during the research project, or at its conclusion, for example:

- the AEC and institutional designated staff responsible for rehoming have good reason to believe that rehoming would not be in an animal's best interests, with consideration given to the quality of life, and life expectancy of the animal, including instances where the cumulative impact from use could have negative welfare outcomes for an animal
- when the behaviour of an animal indicates that it may pose a risk to public safety.

It is recommended that the research institution, rehoming organisation and prospective owner review the relevant legislation prior to any alpacas being rehomed. Current NSW animal welfare legislation is available at the NSW DPI [Animal welfare regulation](#) webpage.

When rehoming alpacas, the properties of new owners require a registered [Property Identification Code \(PIC\)](#).

During the research project

Planning for the eventual rehoming of animals involved in research should be integrated into the animals' care plan from the beginning of their involvement in any study. The rehoming coordinator should ensure that appropriate monitoring of the programs of socialisation, habituation, environmental enrichment and training are occurring during the research project to increase the chance of successful rehoming. These programs should be outlined in the accredited research establishment's procedure for the preparation of animals for rehoming. The rehoming coordinator

should ensure early remedial action is taken, if possible, where an animal is deviating from the desired outcomes of those programs.

Periodic behavioural assessments should be carried out and recorded by animal care staff during the research project. There may be benefits for team morale in involving staff in the rehoming process – e.g. by forming a small rehoming committee. Staff should record individual animal behavioural observations, to be used when assessing the suitability of animals for rehoming. Where these observations reveal animals are stressed, efforts should be made to remove or reduce the stressors if possible.

Alpacas should receive all applicable routine prophylactic treatments, including vitamin D supplementation, vaccinations and parasite control.

Following conclusion of use

If animals are to be desexed and this has not occurred prior to the commencement of, or during, the research project, then determination of whether this is required should occur at the conclusion of the research project.

A final assessment of animals should not be undertaken until the animals have been given time to recover in a suitable environment that provides for normal species-specific behaviours.

Prior to making a final assessment, efforts should also be made to rehabilitate animals with known problem behaviours or that have health conditions that temporarily make them unsuitable for rehoming. It should be noted that rehoming organisations may be prepared to take on or assist in rehabilitating such animals.

Physical assessment of alpacas

Alpacas should be assessed by a veterinarian as being physically healthy before rehoming. A physical assessment should consider:

- general demeanour
- movement and mobility: should walk with normal mobility and range of movement
- neurological soundness: general reflexes (sight, hearing), not ataxic (uncoordinated)
- body condition score, for example, a score out of 5:
 1. Very thin – severely concave between spine and ribs, ribs easily felt, chest hard and bony with no fat, and a very increased space between legs
 2. Moderately thin – slightly concave between spine and ribs, ribs easily felt, chest with little fat, some loss of muscle, and increased space between legs
 3. Good condition – neither concave or convex between spine and ribs, ribs felt with slight pressure, chest firm and muscular, and straight line between front legs
 4. Overweight – convex (roundness) between spine and ribs, ribs difficult to palpate, rounded and soft feeling chest, and inner thighs smooth and less defined
 5. Obese – difficult to palpate between spine and ribs, firm pressure needed to feel ribs, rounded soft chest, large area of contact between hind legs, with little or no definition of inner thighs; may also have difficulty walking properly
- fleece and skin: look for signs of abnormal coat (including inappropriate fleece length for the season), alopecia, ectoparasites, inflammation, lumps, growths, signs of infection, lesions and trauma
- respiratory tract: no coughing, no nasal discharge
- eyes: should be clear, have symmetrical and normal pupil response, and be free of discharge

- gums and eyelids: pink colour rather than pale or grey
- dentition: no obvious issues with teeth, bite or chewing, including excessive overgrowth of teeth, especially the front teeth. Male alpacas should have fighting teeth removed
- ears: should have no discharge, inflammation or foul odour
- limbs: no obvious lameness, swelling or pain on palpation
- nails and footpads: nails are a reasonable length and free of cracks, or deformity. Toes and footpads are free of injury and infection
- faeces: pelleted rather than runny or loose
- abdomen appearance: not swollen or bloated
- any history of diarrhoea, vomiting, inappetence or unusual drinking or urination
- general heart and lung field auscultation/exams: no issues
- any other abnormality

The significance and appropriate management of any abnormal findings must be determined with veterinary advice. Base rehoming decisions on the expected impact on the alpaca's long-term quality of life.

Behavioural assessment of alpacas

Alpacas assessed as physically sound should be behaviourally assessed prior to rehoming, to gauge their likelihood of adapting to post-research life.

It is important to consider the context in which this behavioural assessment takes place. For an animal that has little experience of novel environments and unfamiliar people it would be reasonable to expect it will find many environments unsettling. If it recovers quickly and is actively engaged with its normal behaviour towards humans and their environment, it may be more resilient and therefore more suitable for rehoming.

Where possible, assessment of animals should take place in an environment outside normal territory and housing. Where possible, conduct behavioural assessments on animals that are not stressed to better understand their suitability for rehoming.

This assessment should be undertaken by people that are familiar with species-typical behaviour (usually a suitably qualified animal care staff member and a veterinarian). It should take into account the history of behavioural assessments carried out and recorded over time by animal care staff since the commencement of the research project.

Reasons for conducting behavioural assessments include:

- assessing animals for rehoming
- assessing what kinds of environments may be suitable for the animal (e.g. homes where they can be separated from small children or other animals)
- understanding the temperament and needs of the animal
- exploring whether the animal displays any behaviours that have bearing on their rehoming.

A behavioural assessment should consider whether the alpaca:

- interacts positively with a variety of people who are familiar and unfamiliar
- accepts or tolerates handling and petting
- can be held for husbandry tasks (excluding shearing)
- has an abnormally large flight distance

- follows people, stares or flips its tail over its back - this is a sign that the alpaca is not happy with human interaction
- rears at, or bites, people
- has a history of positive interactions with other alpacas in the animal research establishment (some males show continuous aggression towards other alpacas)
- displays normal feeding behaviour

Presence or absence of one of these behavioural characteristics should not by itself ordinarily preclude rehoming. Potential recipients who are aware that an animal does not possess preferred behavioural characteristics may still wish to rehome it.

It is the responsibility of the establishment to decide on the applicability of specific temperament assessment tools to its situation.

The response of an animal is best recorded as a description of behaviour (e.g. kicked or charged), rather than an interpretation of the behaviour or emotion (e.g. angry, scared, excessively reactive or aggressive) so that the animal is judged as objectively as possible.

An alpaca with undesirable behaviours can often be rehomed satisfactorily when the recipient has been informed and is prepared to accept such behaviours. Experienced recipients often have the capacity to improve such behaviours.

Fear of humans can be reduced if alpacas have regular positive interactions with animal carers.

Behaviour can change dramatically after rehoming. Stressors tend to be reduced living outside of a research establishment - mostly due to the fact that animals can usually exhibit a greater range of natural behaviours in the rehoming environment and housing.
